(54) Title: CLEATED SOLE FOR AN ATHLETIC SHOE

(57) Abstract

An improved athletic shoe sole (10) of the type having annular cleating is disclosed. The sole (10) includes an annular cleat set (21) projecting from the main sole surface (19) and disposed along a substantially circular path (25) which encompasses a major area of the toe and ball-of-the-foot portions (17, 15), the set (21) having a plurality of cleat nodes (23), each of which is arranged in a substantially abutting relationship to at least one adjacent cleat node (23). Each cleat node (23) has a distal end or tip (39) spaced from the main sole surface (19) and first and second edges (45a, 45b) on opposite sides of the distal end (39) with proximal ends (47) terminating on the circular path (25). Improved pivotability and traction characteristics are provided.

DESIGNATIONS OF "DE"

Until further notice, any designation of "DE" in any international application whose international filing date is prior to October 3, 1990, shall have effect in the territory of the Federal Republic of Germany with the exception of the territory of the former German Democratic Republic.

CLEATED SOLE FOR AN ATHLETIC SHOE

Field of the Invention

25 This invention is related generally to athletic shoes of the type having cleats for penetrating ground engagement and, more specifically, to athletic shoes with cleats facilitating pivoting movement.

Background of the Invention

30 Many athletic shoes used for field sports, such as football, soccer, lacrosse, baseball and softball, have a number of typically truncated cone-shaped cleats for the purpose of increasing traction. Cleats dig into the turf to prevent slipping during starting, stopping, and cutting maneuvers.

35 However, in addition to providing desirable traction for starting, stopping and cutting, such cleats typically

-2-

1 provide very undesirable resistance to pivoting. This can
be a disadvantage in at least two ways.

First, the resistance of many prior art cleating
arrangements to turning movements can create stresses
5 within the leg when unwanted torque or force is applied to
the athlete, particularly to the athlete's leg. Injuries,
particularly knee and ankle injuries, can result if a
twisting movement is forcibly applied to a leg at a time
when the cleats are firmly planted in the turf and release
10 is difficult or impossible.

Second, when pivoting is inhibited, maneuverability
of the athlete is limited, thus making performance less
than it could be. Enhancing the ability of a player to
pivot while still maintaining good traction and foot
15 stability can greatly increase effectiveness on the field.

Recent athletic shoe cleating developments of Michael
L. Tanel, the inventor herein, involving annular cleating
provided a combination of greatly improved pivotability and
excellent traction. These developments tend to reduce the
20 chance of athletic injuries and significantly improve
maneuverability on the field. Examples of such cleating
are disclosed in United States Patent Nos. 4,577,422,
4,653,206, 4,660,304, 4,669,204, 4,723,365 and 4,748,752.

The improvement in pivotability made possible with
shoes in accordance with the principles of such patents is
25 dramatic, and such shoes give the athletes wearing them a
natural feeling of freedom together with good feeling of
traction for stopping, starting and cutting.

Despite the improvements which these developments
represent, additional improvement is needed to provide
30 functional advantages not realized or fully realized in the
prior art. Certain conditions and situations must be
addressed and are addressed by the improvements of this
invention.

35 One significant concern regarding cleated soles for
athletic shoes, including those disclosed in the patents
noted above, relates to the degree and ease of penetration

-3-

1 of cleats. Ease of penetration has a significant effect on
how well a shoe functions. If there is insufficient ground
penetration or if ground penetration is difficult, there
may be less traction than is desirable and less contact
5 with the turf than is needed for the best possible
fixed-position pivoting.

In this regard, consideration must be given to, among
other things, the total area of the cleat ends, that is,
the total area of the distal surface(s) of the cleat or
10 cleats. Generally speaking, the greater the total end area
bearing on the ground, the more difficult it may be for a
cleat to penetrate the ground; the smaller the total end
area bearing on the ground, the easier it may be for a
cleat to penetrate. This effect is accentuated when the
15 ground is hard.

Sharpening the distal end(s) of cleat(s), whether the
shoe has discrete cleats or an annular cleat with an
annular distal edge, tends to reduce the total area of
cleat distal surface. However, it may also cause concern
20 about injury from player contact with such sharp edges.
This latter concern particularly arises in the cases of
hard plastic or metal cleats.

Whether in pivoting motions or non-pivoting motions,
maintenance of stability and traction is important under
25 all conditions. Particular consideration must be given to
the traction available from an athletic shoe sole when the
wearer is playing on grassy turf with a very compact and
hard underlying earth surface. Little if any earth
penetration may be possible under such conditions,
depending on the extent of turf hardness and compaction.
30 The concern about hard ground under grassy turf is
particularly significant when the grass is wet, as often
occurs late in the evening or early in the morning because
of dew.

35 The design of the sole can and should address such
condition. When penetration is difficult, traction may
depend in part on the extent of rubber "grab" on the ground

-4-

1 and in part on the extent of "tangle" which is possible
with the grass. When the grass is also wet, rubber "grab"
is minimized and "tangle" becomes more important to an
athlete's traction. Of course, the athlete does not wish
5 to sacrifice pivotability under these conditions any more
than he does under other turf conditions.

Another important consideration relates to the degree
to which the underlying turf is destroyed when played upon
by wearers of cleated shoes. With standard cleating
10 arrangements, when pivoting occurs considerable ground or
turf destruction can occur; that is, the turf may be ground
up. This is not only harmful to the ground, but in itself
causes a loss of foot traction. With an annular cleat,
ground destruction is minimized, thus enhancing foot
15 traction. There is a need to have the benefits of both
sorts of cleats without unduly destroying turf.

While free pivotability is highly desirable, some
athlete's would like there to be a degree of control in
such pivotability. Providing a cleating arrangement with a
modicum of initial resistance to pivoting would be regarded
20 as desirable by some. However, generally free pivotability
beyond that point is considered extremely important. Once
again, there is a perceived need for some benefits of
annular cleating combined with some benefits of old-style
standard cleating arrangements.
25

Still another concern relates to the strength of
cleats. Cleat bending and breakage can be a problem. It
is considered very beneficial, of course, for cleats to be
highly resistant to bending and breakage. Improvements in
cleat structural strength are desirable.
30

In very soft ground, the lateral profile of some
standard cleats of the prior art is sometimes too small to
provide a sufficient level of resistance to through-ground
sliding. Ground can be displaced when side pressure
occurs, thus providing a failure of traction. Providing
35 cleats with greater resistance to such side pressure would
be highly desirable.

-5-

1 Still another problem with certain cleated shoes of
the prior art is that the pressure of the individual cleats
can be felt by the foot of the athlete. Because of this,
shoe comfort is reduced. The aforementioned annular cleats
5 tend to overcome this problem, but for shoes with discrete
cleats, this problem can be significant.

A few general comments are in order before turning to
a description of this invention. In particular, a brief
description of the foot and its pivoting and planted
10 positions will be helpful. This can serve as an aid in
understanding preferred embodiments of this invention.

The sole of the foot includes four portions. These
are, in order from back to front: the heel portion; the
arch portion; the ball-of-the-foot portion; and the toe
15 portion. The heel and ball-of-the-foot portions are those
portions which share most if not all of the player's weight
when the player is in a normal standing position with feet
generally flat on the ground. In such position, the arch
portion and toe portion bear little if any weight.

20 When a player is "on his toes" in a "ready" position,
virtually all of the player's weight is normally shared by
the toe portion and the ball-of-the-foot portion. The same
is usually true when a player is "digging" in a running
action. Indeed, when a player is in the ready position,
25 the juncture of the phalanges (toe bones) and the
metatarsals is the center of weight bearing. In other
words, the center of weight bearing in the forward portions
of the foot actually moves forward when a player shifts to
the ready position.

30 The sole of an athletic shoe has portions immediately
below these four portions of the foot which may be
designated, and herein are designated, by the same terms.

Objects of the Invention

35 It is an object of this invention to overcome some of
the problems and shortcomings of the prior art, including
those mentioned above.

-6-

1 Another object of this invention is to provide an improved athletic shoe sole.

 Another object of this invention is to provide an athletic shoe having both improved pivotability and
5 excellent traction.

 Another object of this invention is to provide an improved athletic shoe which tends to reduce the risk of certain common injuries of athletes, particularly knee and ankle injuries.

10 Another object is to provide an improved athletic shoe of the type having annular cleating.

 Another object of this invention is to provide an improved annular-cleated athletic shoe with enhanced ground penetration.

15 Still another object is to provide an athletic shoe sole exhibiting both good traction and pivoting characteristics on grass-covered hard earth, particularly when such grass is wet.

 Another object of this invention is to provide an athletic shoe with annular cleating which nevertheless
20 exhibits good "tangle" traction with turf.

 Yet another object is to provide an improved annular-cleated shoe having both excellent "grab" traction and excellent "tangle" traction.

25 Another object of this invention is to provide improved ground penetration in an annular-cleated shoe without sharpening the distal edge of annular cleating.

 Another object is to provide an cleated athletic shoe combining certain benefits of standard cleating with certain benefits of annular cleating.
30

 Another object is to provide an athletic shoe with improved ground penetrability which avoids or minimizes turf destruction and the resulting traction loss.

 Another object of this invention is to provide an improved annular-cleated shoe with excellent pivotability
35 which nevertheless provides what some perceive to be a desirable degree of initial resistance to pivoting.

-7-

1 Still another object of this invention is to provide
a cleated athletic shoe having cleating with excellent
strength and resistance to bending and breakage.

 Another object of this invention is to provide an
5 improved cleated shoe with wide cleat profile to avoid
unnecessary through-ground sliding, thus enhancing stopping
and starting traction.

 Yet another object of this invention is to provide a
cleated athletic shoe exhibiting excellent sole comfort.

10 These and other important objects will be apparent
from the descriptions of this invention which follow.

Summary of the Invention

 This invention is an improved athletic shoe sole for
15 field sports providing excellent controlled pivotability
and traction in a commercially desirable form. The
invention is an improvement in athletic shoe soles of the
type having annular cleating.

 The invention provides enhanced ground penetration,
20 and resulting improvements in traction and pivotability.
The sole of this invention also provides both good traction
and pivoting characteristics on grass-covered hard earth,
with significant improvement provided even when such grass
is wet. Improved "tangle" and "grab" traction are provided
25 in a sole of the type having annular cleating. Improved
traction is provided without sharpening the distal edge of
annular cleating. The soles of this invention minimize
turf destruction even while providing excellent traction
characteristics.

 The soles of this invention, while having excellent
30 pivoting characteristics, also provide what some perceive
to be a desirable degree of initial resistance to pivoting.
This gives an even greater feeling of control to some
athletes. The cleating arrangement of this invention
provide a wide cleat profile and thus avoid through-ground
35 sliding. This enhances traction, particularly stopping and
starting traction.

-8-

1 The soles of this invention are comfortable to wear,
substantially avoiding any feeling of individual cleats as
can occur with certain shoes of the prior art. The annular
cleating of this invention also has excellent strength and
5 resistance to bending and breakage. This is due in part to
wide base dimensions.

 The inventive sole has an annular cleat set which
projects from the main sole surface and is disposed along a
substantially circular path which encompassing a major area
10 of the toe and ball-of-the-foot portions. The annular
cleat set has a plurality of cleat nodes, each of which is
arranged in a substantially abutting relationship to at
least one adjacent cleat node. Each of the cleat nodes has
a distal end spaced from the main sole surface and first
15 and second edges on opposite sides of the distal end. The
edges having proximal ends which terminate substantially on
the circular path.

 The first and second edges, sometimes referred to
herein as leading and trailing edges because of their
20 relationship to the cleat node and the ground during
pivoting, function to cut into the turf, thereby reducing
initial resistance to penetration by the cleats. The
inventive sole thereby exhibits excellent initial
penetration as well as traction and pivotability.

25 In a first preferred embodiment, adjacent pairs of
cleat nodes are arranged to be in substantial abutment at
the base portion of the nodes, that is, where the cleat
nodes join the main sole surface. In a second preferred
embodiment, cleats abut at the shoulder, that is, at a
30 region generally midway between the base portion and the
distal end (or "tip") of the cleat. This second embodiment
is somewhat more "aggressive" than the first embodiment in
its ability to maximize traction. Nevertheless, its
configuration exhibits substantially the same advantages as
described above with respect to the first embodiment. In a
35 third embodiment, cleat nodes abut at their distal ends
tips.

-9-

1 As used herein, the expression "substantially
abutting relationship" means any one of the foregoing
relationships. The term also describes the relationship of
cleat nodes which may be slightly spaced from one another
5 at their base portions, or any combination of the
foregoing.

A preferred feature of the second embodiment is that
the cleat nodes located on the circular path in a position
adjacent to the arch portion of the sole are in abutment at
10 their base portions rather than at the shoulder portions,
as with the other cleat nodes of such embodiment. The
resulting V-shaped spaces between cleat nodes in this area
extend from the cleat tips to the sole surface and help
prevent the sole from adhering to the turf by suction, as
15 might otherwise occur on a muddy field. Such spaces allow
air venting to help prevent the "clapping" sound which can
result from trapped air, particularly when a player is
running backwards.

All non-cleated areas of that portion of the sole
20 area enclosed by the circular path are preferably
coincident with the main sole surface; that is, such
surfaces are not built up. This allows full turf
penetration by the cleats.

Each of the cleat nodes has a base portion joined to
25 the main sole surface. The base portion of each cleat node
has a length measured generally along the circular path of
the cleat set and a thickness measured generally radially
to such path. The length is substantially greater than the
thickness, thus providing excellent pivotability of the
sole with good resistance to forces urging the sole
30 laterally or longitudinally.

Controlling the relative length and thickness as
described results in a cleat which presents a relatively
small frontal area when the sole is being pivoted, thereby
reducing pivoting effort. In contrast, the circumferential
35 profile of the cleat nodes is quite large, thereby
providing a high degree of stability and traction.

-10-

1 In a highly preferred embodiment, the cleat nodes are
tapered to blunt, rather than pointed, distal ends. This
configuration optimally resolves the conflicting concerns
relating to ease of penetration on the one hand and
5 avoidance of player "spiking" injuries on the other.

 In a highly preferred embodiment, each cleat node has
multiple planar surfaces and leading and trailing edges
each formed by the acute-angle intersections of pairs of
such planar surfaces. The leading and trailing edges are
10 substantially coincident with a projection of the circular
path and form acute angles with the main sole surface. The
resulting cleat node edges facilitate initial ground
penetration. In addition, these edges slice rather than
"punch" through the turf as the sole is pivoted.

15 Because of the abutting relationship of the cleat
nodes and the angular arrangement of the edges, some highly
desirable results are accomplished. First, resistance to
initial penetration increases gradually rather than
instantaneously as the cleat node first contacts and then
20 penetrates the turf. Second, only slight pivoting rotation
of the sole causes a trailing cleat node to enter and
follow a path cut by a leading cleat node; therefore, there
is a reduction in resistance to pivoting movement following
slight initial resistance during initial rotation.

25 In addition, the unique design of the inventive sole
tends to preserve rather than destroy turf. The structural
integrity of the earth beneath the sole tends to be
preserved and good traction is maintained rather than
reduced.

30 In order to maximize the stability of the sole
against lateral forces, the outer surface of at least one
of the cleat nodes is generally coincident with the lateral
side portion of the sole. An outer surface of at least one
other cleat node is generally coincident with the medial
side portion of the sole. Stated another way, the cleat
35 nodes on the medial side and lateral side portions of the
soles preferably have maximum spacing therebetween. This

-11-

1 helps reduce the possibility or the severity of ankle-twist injuries.

To help assure that the athlete enjoys excellent sole flexibility in the ball-of-the-foot and toe portions, it is preferred that the cleat nodes be arranged to promote such flexibility while yet maintaining a good capability for stopping, starting and cutting. In certain embodiments of this invention, each adjacent pair of abutting, tapered cleat nodes defines a generally V-shaped space between them. The annular cleat set includes a plurality of opposed pairs of such spaces forming a plurality of cross-sole breaks in the annular cleat set.

The configuration of the inventive athletic shoe sole and of the cleat nodes forming a part of the sole may be readily adapted to accommodate specific requirements. For example, the angles of taper of leading and trailing edges may be changed, the degree of sharpness of such edges may be modified and/or the cleat tip may be more or less blunted or pointed.

In some cases, it may be desirable to taper cleat nodes non-uniformly so that the profiles of the leading edges are different than the profiles of their trailing edges. This would serve to make pivoting easier in one direction than another, which may be desirable for athletes playing certain positions. Varying sharpness of leading and trailing edges can provide the same result.

Little or no spacing between cleat nodes is highly preferred. In such cases, there is little if any of the main sole portion lying exposed along the circular path followed by the annular cleat set. Thus, the cleat set of this invention, for all practical purposes, forms a substantially continuous ring despite the characteristics of the cleat nodes therealong.

Brief Description of the Drawings

15

Detailed Descriptions of Preferred Embodiments

 The figures illustrate a preferred athletic shoe sole 10 in accordance with this invention.

20 Referring first to FIGURE 2, the sole 10 has four portions which are defined by the portions of the foot adjacent to them. These sole portions are: the heel portion 11; the arch portion 13; the ball-of-the-foot portion 15; and the toe portion 17. The upper portions of the shoe are not illustrated.

25

 Referring now to FIGURE 1, the lower surface of the sole 10, which contacts the surface of the playing field, includes a main sole surface 19 which is a generally flat, even surface from which an annular cleat set 21 projects. The cleat set 21 has a number of cleat nodes 23 which are integrally formed with the main sole surface 19 in a molding process of well-known type. The sole 10 is made of material which is tough and wear resistant but which can flex in the normal manner depending upon how weight is applied to it. The sole 10 is preferably formed of polyurethane or rubber.

30

35

-13-

1 A plurality of cleat nodes 23 project from the main
sole surface 19 and are disposed along a substantially
circular path 25. This path 25 encompasses a major area of
toe and ball-of-the-foot portions 17 and 15, respectively,
5 and is centered on the juncture of such portions. Each
cleat node 23 is arranged in a substantially abutting
relationship to at least one adjacent cleat node 23 for
providing improved engagement between the sole 10 and an
earthen surface such as turf. Improved engagement results
10 because of the relatively large number of cleat nodes 23
projecting from the sole 10, among other things.

 For sports involving frequent and sudden shifts in
body position or direction of movement, it is preferred
that the arrangement of the cleat nodes 23 is selected to
15 maximize the lateral stability of the shoe. To that end,
an outer surface 27 of at least one of the cleat nodes 23
is generally coincident with the lateral side portion 29 of
the sole 10. An outer surface 27 of at least another one
of the cleat nodes 23 is generally coincident with the
20 medial side portion 31 of the sole 10. Improved lateral
shoe stability results and this feature aids in avoiding
ankle injuries or in lessening their severity.

 It is also preferred that the sole 10 exhibit a high
degree of cross-sole flexibility, particularly at and near
25 the junction of toe and ball-of-the-foot portions, 17 and
15, respectively. Accordingly and in the first and second
embodiments, shown in FIGURES 1 and 7 respectively, a first
opposed pair of V-shaped spaces 33 defines one break (or
flexing line or region) and a second opposed pair of
30 V-shaped spaces 35 defines another break located forward of
the first. The flexibility of the sole 10 is thereby
preserved while yet maintaining an excellent traction
capability.

 Referring next to FIGURES 3, 4, 5 and 6, a preferred
35 cleat node 23 is shown to include a base portion 37, a
distal end or tip 39 and a shoulder 41 located generally
midway between the base portion 37 and the tip 39. Each

-14-

1 cleat node 23 includes multiple planar surfaces 43 and
edges 45 at the intersections of pairs of such planar
surfaces 43. In particular, a cleat node 23 includes a
first edge 45a and a second edge 45b, each formed by the
5 intersection of two planar surfaces 43 having an acute
included angle between them. The proximal ends 47 of the
first edge 45a and second edge 45b terminate on the path 25
and each of the edges 45a, 45b cooperates with the main
sole surface 19 to likewise define an acute included angle
10 "A" between them. The tip 39 is a flat surface which is
diamond-shaped as shown in FIGURE 3. This surface may be
smooth or, preferably, cross hatched to a shallow depth for
improved traction.

Referring generally to FIGURES 3-5 and particularly
15 to FIGURES 4 and 5, a highly preferred cleat node 23 is
tapered in two dimensions D1, D2. A first dimension D1 is
measured along the base portion 37 generally parallel to
the path 25. It will be appreciated that if measurement is
taken in a plane parallel to the path 25 and at progressive
20 points along the first and second edges 45a, 45b, where the
edges 45a, 45b intersect with the plane the dimension D1
between points on those edges 45a, 45b diminishes as the
points of measurement move upward from the base portion 37
to the tip 39. Similarly and referring particularly to
25 FIGURES 3 and 4, a second dimension D2, cleat node
thickness, may be similarly measured generally radially to
the path 25 and it will be noted that the thickness of the
cleat node 23 also diminishes as the points of measurement
are moved upward from the base portion 37 to the tip 39.

30 Several benefits arise from the use of a cleat node
23 having the described configuration. Referring
particularly to FIGURES 1, 3 and 4, it is apparent that the
tip 39 has a relatively small surface area. As the tip 39
first makes contact with the turf, it tends to readily
penetrate the turf, especially soft turf. Penetration is
35 aided by the fact that the first and second edges 45a, 45b
progressively slice the turf as the depth of penetration

-15-

1 increases. This combination of a tip surface with a
relatively small area and of first and second edges 45a,
45b exhibiting wedge-like or knife-like characteristics
results in good penetration characteristics.

5 Pivoting movement causes the annular cleat set 21 to
move about a center cleat 49 which is located at or near
the center of the circular path 25. As a cleat node 23
moves in either direction, its first edge 45a or second
edge 45b, whichever is leading, cuts through the turf. The
10 corresponding edge of the adjacent trailing cleat node 23
thereafter enters and follows the path cut by the leading
cleat node 23. Pivoting effort is thereby reduced.

Referring especially to FIGURE 4, the profile of a
cleat node 23 as seen spanning the circular path 25 of the
15 annular cleat set 21 is relatively small and this fact also
aids in the ability of the cleat node 23 to more easily
advance through the turf as the sole 10 is pivoted.

As explained above, a preferred sole 10 not only
facilitates pivoting movement without the imposition of
20 undue stress on the athlete's leg but also provides
stability and traction for foot movements not involving
pivoting. Referring particularly to FIGURE 5, the profile
area of a side of the cleat node 23 is relatively large and
this provides a substantial surface to resist slipping
25 during stopping, starting, and cutting.

Still another benefit of the described cleat node 23
configuration may be attributed to its tapered shape. That
is, its base portion 37 has an area which is significantly
larger than that of the surface of the tip 39. This "broad
30 shouldered" configuration makes the cleat node 23 highly
resistive to forces which may bend, twist or otherwise
deform the cleat node 23 and impair traction.

One of the most difficult of all playing field
conditions is presented when very hard earth is covered
with wet grass. This most frequently occurs upon the
35 formation of dew. Not only is it difficult to penetrate
the ground with any sort of cleat configuration, but

-16-

1 conventional smooth-surfaced, conical cleats have a low
coefficient of friction in contact with wetted grass. With
the annular cleat sets 21 described herein, the multiple
edges 45 on each cleat node 23 combined with an arrangement
5 of cleat nodes 23 in an abutting relationship, with or
without V-shaped spaces 35 therebetween, helps "tangle"
with blades of grass. Improved traction results.

With respect to the first embodiment, it should also
be appreciated that during rare but very strenuous
10 movements, the sole 10 may become severely flexed along any
line passing through the center cleat 49. Many cleat nodes
23 may not then be in contact with the turf. Even in that
event, the sole 10 maintains at least three cleat nodes 23
in turf contact for helping the athlete maintain footing.

15 Referring next to FIGURE 7, a second embodiment of
the athletic shoe sole 10 includes cleat nodes 23 arranged
in a substantially abutting relationship to at least one
adjacent cleat node 23. In the second embodiment and for
all but one of the cleat nodes 23, the abutting
20 relationship occurs at the shoulder portion 41 rather than
at the base portion 37. For any given size of shoe sole
10, this provides a greater cleat "density" and results in
a sole 10 which more aggressively grips the turf. In the
embodiments described above, that portion of the main sole
25 surface 19 which is encompassed by the circular path 25 is
not built up; that is, it lies generally on the same plane
as those portions of the sole surface 19 lying outside the
circular path 25.

Referring to FIGURE 7, it will be noted that in this
30 second embodiment, most of the cleat nodes 23 abut at the
shoulder 41 rather than at the base portion 37. Unless
special precautions are taken, air may become entrapped
within the space encompassed by the annular cleat set 21,
as previously explained. Accordingly, one cleat node 23a,
35 preferably located at the rear part of the circular path
25, is arranged to abut adjacent cleat nodes 23b at the

-17-

1 base portion 37 or to be slightly spaced therefrom. This
arrangement provides a plurality of air passages to prevent
air entrapment.

Yet other arrangements of the inventive athletic shoe
5 sole 10 are possible in view of the foregoing. For
example, a sole 10 configured for use on artificial turf
may employ concentric rings of cleat nodes 23 at the
forefoot, and perhaps also on the heel. Still another
variation may involve the use of cleat nodes 23 of slightly
10 different size and/or physical arrangement. For example,
cleat nodes 23 may be sized and arranged to define a pair
of spaces adjacent the lateral sole portion 29 but only a
single space adjacent the medial sole portion 31. The
resulting spaces would provide for sole flexibility by
15 defining a "V", the ends of which are at the lateral sole
portion 29 and the apex of which is at the medial sole
portion 31.

Referring to FIGURE 8, a third embodiment involves
arranging cleat nodes 23 in an abutting relationship at the
20 tip 39 or distal end. Of the three embodiments, this third
embodiment maximizes the area which initially contacts the
turf and the area forming the bearing surface during
pivoting movement. Therefore, this third embodiment has
the least resistance to pivoting effort. However, the
25 presence of its multiple edges 45 in engagement with the
turf, including wet grass, provides improved traction over
earlier shoe soles.

While the principles of this invention have been
described in connection with specific embodiments, it
should be understood clearly that these descriptions are
30 made only by way of example and are not intended to limit
the scope of the invention.

1 CLAIMS:

1. In an athletic shoe sole of the type having a main sole surface and cleats extending therefrom, and
5 having heel, arch, ball-of-the-foot and toe portions, the improvement comprising:

-an annular cleat set projecting from the main sole surface and disposed along a substantially circular path which encompasses a major area of the toe and
10 ball-of-the-foot portions, the set having a plurality of cleat nodes each of which is arranged in a substantially abutting relationship to at least one adjacent cleat node; and
-each of the cleat nodes having a distal end spaced
15 from the main sole surface and first and second edges on opposite sides of the distal end, the edges having proximal ends which terminate substantially on the circular path.

2. The athletic shoe sole of claim 1 wherein each of
20 the cleat nodes comprises a base portion which is joined to the main sole surface and has a length measured generally along the path and a thickness measured generally radially to the path, the length being substantially greater than
25 the thickness, whereby the cleat set provides excellent pivotability of an athletic shoe and excellent resistance to forces urging the shoe laterally or longitudinally.

3. The athletic shoe sole of claim 2 wherein when
30 the cleat nodes are in contact with the ground, each of the edges defines with the ground an acute included angle, thereby reducing resistance of the sole to pivoting motion.

4. The athletic shoe sole of claim 3 wherein the
35 abutting relationship occurs at the base portions of abutting cleat nodes.

-19-

1. 5. The athletic shoe sole of claim 3 wherein:
-each of the cleat nodes includes a shoulder portion
located intermediate the distal end and the main sole
surface; and
5 -the abutting relationship occurs at the shoulder
portions of abutting cleat nodes.

6. The athletic shoe sole of claim 3 wherein the
abutting relationship occurs at the distal ends of the
10 abutting cleat nodes.

7. The athletic shoe sole of claim 1 wherein each of
the first and second edges forms an acute angle with the
main sole surface, thereby further facilitating pivoting.

-20-

1 8. In an athletic shoe sole of the type having a
main sole surface and cleats extending therefrom, and
having heel, arch, ball-of-the-foot and toe portions, and
opposite lateral and medial side portions, the improvement
5 comprising:

-an annular cleat set projecting from the main sole
surface and disposed along a substantially circular
path which encompasses a major area of the toe and
ball-of-the-foot portions, the set having a plurality
10 of tapered cleat nodes, at least one of said cleat
nodes having a radially-outer surface generally
coincident with the medial side portion and at least
one other of said cleat nodes having a radially-outer
surface generally coincident with the lateral side
15 portion; and

-each adjacent pair of tapered cleat nodes defining a
generally V-shaped space therebetween, a plurality of
opposed pairs of the spaces forming a plurality of
cross-sole breaks in the annular cleat set.

20 9. The athletic shoe sole of claim 8 wherein each of
the cleat nodes is tapered in two dimensions, a first
dimension measured generally parallel to the path and a
second dimension measured generally radially to the path,
25 thereby providing a tip of reduced area.

10. The athletic shoe sole of claim 8 wherein:
-each of the cleat nodes includes multiple planar
surfaces and edges at the intersections of pairs of
the planar surfaces;
30 -the edges include a leading edge and a trailing
edge, said leading and trailing edges each formed by
intersection of two of said planar surfaces having an
acute angle therebetween; and
-each of the leading and trailing edges defines an
35 acute angle with the main sole surface,
whereby ground penetration and pivoting movements are
facilitated.
